

PFAS and Microplastics in WWTP

Drs. Zhiming Zhang, Kauser Jahan, and Cheng Zhang

Both per- and polyfluoroalkyl substances (PFAS) and microplastics are emerging contaminants of concern to the environment, which have recently received global attention due to their many detrimental impacts on aquatic ecosystems. Although wastewater treatment plants are designed to treat contaminants in wastewater before discharging into the receiving water bodies, PFAS and microplastics are not effectively removed, making wastewater treatment plants as sources of PFAS and microplastics contamination in the environment.

- Literature review of PFAS and microplastics in wastewater treatment plants will be conducted.
- Water and sludge samples from different stages of wastewater treatment train will be analyzed for PFAS, including PFAS precursors.
- Simultaneously, microplastics will be characterized in terms of sizes, types, and quantities.
